

How To Safely Clean Windows Registry

The system registry in a Windows machine is a database that keeps tabs on all the software and configurations of programs on a computer. Any other hardware configurations or other startup information the computer needs to keep track of will be retained in such a registry. But as consumers find, the bigger the registry, the bigger the "slowdown" effect computers experience. Thus, cleaning out the registry is a vital task to a computer's health.

A system registry is created in order to create order, organization, and make things functional. Just like a good program can make use of the registry for good tactics, malicious software can make use of the registry for bad. And because malware can "hide" in the registry, actually removing the threat can be near impossible. In such a case, the use of a registry cleaner will be necessary to keep a healthy computer.

The first way to clean a system registry is to simply use the built-in editor that comes with Windows. This program is called the Windows Registry Editor, and can be found by typing "regedit" in the "Run Command" window. It should be noted, however, that the registry editor can be very dangerous for those who don't know how to use it, and irreversible damage can be caused to one's machine as a result of tampering with it.

A time saving option would be to simply use a registry cleaning program to automatically do the work for the user. These programs can instantly remove threats and entries that are no longer needed, all while avoiding entries that a computer needs for running correctly. Not only does this save hours of time, but it also ensures that no mistakes are made in removing proper entries, or any threats were left undeleted.

Just like with anything else, exploring one's options in registry cleaning programs is the best way to go about finding the best solution for one's particular needs. It's best to find reviews online, ask friends and family, or consult known technology leaders in your community. Popular names such as Regcure or Registry Mechanic are worth taking a look- although there are many to choose from.

In the end, one should always opt for a registry cleaner that promises to make backups of any changes it makes, as this can repair any otherwise irreparable damage to the registry. Other options may target spyware and malware, and other features to look into include other security preventable features. Some of the better choices of registry cleaners will allow for a free demo or trial period- which should be taken advantage of where given.

In Conclusion

The Windows registry can be a very confusing thing to work with for the everyday computer user. Because this is true, it's best to opt for a registry cleaning program instead of trying to fix one's registry by one's self. This will more than likely cause more damage than help anything, and opting for a registry cleaning program can have more than one area of benefit.
