

GPS on Mobile phone

What doesn't the new mobile Phone have, this latest model day electronic smartphone that has become all the new rage is missing an all important feature - the GPS. You would almost consider this function an actual requirement for a mobile phone but the only requirement a mobile phone needs to have is to be able to call 911 in an emergency. The GPS feature is considered an important one and most smartphones on the market do have it so you ask yourself why Apple didn't include it in its design features.

How can you expand GPS?

The hope of a GPS was always there before its unique releases. It was clear that the iPhone has a Bluetooth connectivity. People thought their problems were resolved just get a Bluetooth handset and connect it to the iPhone then get the correct GPS software and the problem resolved. But not so it turned out that the GPS blue tooth could not connect to the iPhone as Apple products do not traditionally comply with other products this was also the case with the GPS software.

To approach, there is GoogleMaps you can use to a limited level only where you can locate wireless internet, so clearly not universally.
